DEVHINTS.IO Edit

React.js cheatsheet

React is a JavaScript library for building user interfaces. This guide targets React v15 to v16.

Components

```
import React from 'react'
import ReactDOM from 'react-dom'

class Hello extends React.Component {
  render () {
    return <div className='message-box'>
        Hello {this.props.name}
        </div>
    }
}

const el = document.body
ReactDOM.render(<Hello name='John' />, el)

Use the React.js jsfiddle to start hacking. (or the unofficial jsbin)
```

Children

```
<AlertBox>

</AlertBox>

class AlertBox extends Component {
  render () {
    return <div className='alert-box'>
    </div>
```

Import multiple exports

```
import React, {Component} from 'react'
import ReactDOM from 'react-dom'

class Hello extends Component {
    ...
}
```

States

```
constructor(props) {
   super(props)
   this.state = { username: undefined }
}

this.setState({ username: 'rstacruz' })

render () {
   ...
}
```

Use states (this.state) to manage dynamic data.

With <u>Babel</u> you can use <u>proposal-class-fields</u> and get rid of constructor

Data doesn't have to be difficult. Move fast, grow big w/ MongoDB Atlas. Try now.

ads via Carbon

Properties

```
<Video fullscreen={true} autoplay={false} />

render () {
    ...
}

Use this.props to access properties passed to the
```

Nesting

component.

See: Properties

```
class Info extends Component {
  render () {
    const { avatar, username } = this.props

  return <div>
        <UserAvatar src={avatar} />
        <UserProfile username={username} />
        </div>
  }
}
```

As of React v16.2.0, fragments can be used to return multiple children without adding extra wrapping nodes to

```
}
}
```

Children are passed as the children property.

```
class Hello extends Component {
   state = { username: undefined };
   ...
}
See: States
```

the DOM.

Nest components to separate concerns.

See: Composing Components

Defaults

Setting default props

```
color: 'blue'
}

See: defaultProps
```

Setting default state

```
class Hello extends Component {
  constructor (props) {
    super(props)
  }
}
```

Set the default state in the constructor().

And without constructor using Babel with proposal-class-fields.

```
class Hello extends Component \{
```

```
See: Setting the default state
```

Other components

Functional components

```
return <div className='message-box'>
    Hello {name}
  </div>
Functional components have no state. Also, their props
```

are passed as the first parameter to a function.

See: Function and Class Components

Pure components

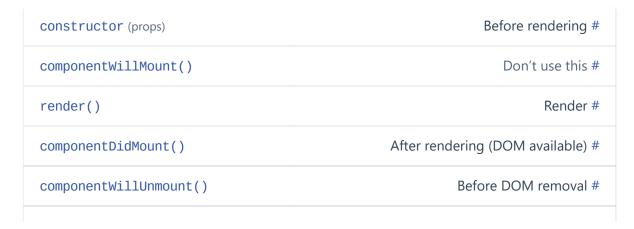

```
import React, {PureComponent} from 'react'
Performance-optimized version of React.Component.
Doesn't rerender if props/state hasn't changed.
See: Pure components
```

Component API

```
this.forceUpdate()
this.setState({ ... })
this.setState(state => { ... })
this.state
this.props
These methods and properties are available for
Component instances.
See: Component API
```

Lifecycle

Mounting

Updating

componentDidUpdate (prevProps, prevState, snapshot)	Use setState() here, but remember to compare props
shouldComponentUpdate (newProps, newState)	Skips render() if returns false
render()	Render
componentDidUpdate (prevProps, prevState)	Operate on the DOM here

```
componentDidCatch() Catch errors (16+) #
```

Set initial the state on constructor(). Add DOM event handlers, timers (etc) on componentDidMount(), then remove them on componentWillUnmount().

Called when parents change properties and .setState(). These are not called for initial renders.

See: Component specs

Hooks (New)

State Hook

Building your own hooks

```
import React, { useState, useEffect } from 'react';

function FriendStatus(props) {
  const [isOnline, setIsOnline] = useState(null);

  useEffect(() => {
    function handleStatusChange(status) {
        contIsOnline(status isOnline);
    }
}
```

Declaring multiple state variables

```
function ExampleWithManyStates() {
   // Declare multiple state variables!
   const [age, setAge] = useState(42);
   const [fruit, setFruit] = useState('banana');
   const [todos, setTodos] = useState([{ text: 'Learn Hooks' }]);
   // ...
}
```

Effect hook

```
setIsOnline(Status.Isonline);
}

}, [props.friend.id]);

if (isOnline === null) {
    return 'Loading...';
}

return isOnline ? 'Online' : 'Offline';
}

Effects may also optionally specify how to "clean up" after them by returning a function.

Use FriendStatus

function FriendStatus(props) {

if (isOnline === null) {
```

See: Building Your Own Hooks

return 'Loading...';

return isOnline ? 'Online' : 'Offline';

If you're familiar with React class lifecycle methods, you can think of useEffect Hook as componentDidMount, componentDidUpdate, and componentWillUnmount combined.

By default, React runs the effects after every render — including the first render.

Hooks API Reference

Also see: Hooks FAQ	
Basic Hooks	
useState(initialState)	
useEffect(() => { })	
useContext(MyContext)	value returned from React.createContext
Full details: Basic Hooks	
Additional Hooks	
useReducer(reducer, initialArg, init)	
<pre>useCallback(() => { })</pre>	
useMemo(() => { })	
useRef(initialValue)	
<pre>useImperativeHandle(ref, () => { })</pre>	
useLayoutEffect	identical to useEffect, but it fires synchronously after all DOM mutations
useDebugValue(value)	display a label for custom hooks in React DevTools
Full details: Additional Hooks	

References

```
class MyComponent extends Component {
  render () {
    return <div>
        </div>
  }
  componentDidMount () {
  }
}

Allows access to DOM nodes.

See: Refs and the DOM
```

DOM Events

```
class MyComponent extends Component {
    render () {
        <input type="text"
            value={this.state.value}

    }
    onChange (event) {
    }
}</pre>
Pass functions to attributes like onChange.
```

See: Events

Other features

Transferring props

```
<VideoPlayer src="video.mp4" />

class VideoPlayer extends Component {
  render () {
  }
}

Propagates src="..." down to the sub-component.

See Transferring props
```

Top-level API

```
React.createClass({ ... })
React.isValidElement(c)

ReactDOM.render(<Component />, domnode, [callback])
ReactDOM.unmountComponentAtNode(domnode)

ReactDOMServer.renderToString(<Component />)
ReactDOMServer.renderToStaticMarkup(<Component />)

There are more, but these are most common.

See: React top-level API
```

JSX patterns

Style shorthand

```
const style = { height: 10 }
return <div style={style}></div>

return <div style={{ margin: 0, padding: 0 }}></div>

See: Inline styles
```

Conditionals

```
<Fragment>
  {showMyComponent
    ? <MyComponent />
    : <OtherComponent />}
```

Short-circuit evaluation

```
<Fragment>
  {showPopup && <Popup />}
  ...
</Fragment>
```

Inner HTML

```
function markdownify() { return "..."; }
<div dangerouslySetInnerHTML={{__html: markdownify()}} />
See: Dangerously set innerHTML
```

Lists

New features

Returning multiple elements

```
You can return multiple elements as arrays or fragments.

Arrays
```

Returning strings

```
render() {
}
```

Errors

```
class MyComponent extends Component {
   ...
```

```
render () {
   // Don't forget the keys!
}

Fragments

render () {
   // Fragments don't require keys!
}

See: Fragments and strings
```

```
You can return just a string.

See: Fragments and strings

Ortals
```

```
Portals

render () {

}

This renders this.props.children into any location in the DOM.
See: Portals
```

```
Catch errors via componentDidCatch. (React 16+)

See: Error handling in React 16
```

Hydration

```
const el = document.getElementById('app')

Use ReactDOM.hydrate instead of using
ReactDOM.render if you're rendering over the output of
ReactDOMServer.
See: Hydrate
```

Property validation

PropTypes

```
import PropTypes from 'prop-types'

See: Typechecking with PropTypes

any Anything

Basic

string

number

func Function
```

Basic types

```
MyComponent.propTypes = {
  email:     PropTypes.string,
  seats:     PropTypes.number,
  callback:     PropTypes.func,
  isClosed:     PropTypes.bool,
  any:     PropTypes.any
}
```

Enumerables (oneOf)

```
MyCo.propTypes = {
  direction: PropTypes.oneOf([
    'left', 'right'
```

Required types

```
MyCo.propTypes = {
  name: PropTypes.string.isRequired
}
```

Elements

```
MyCo.propTypes = {
    // React element
    element: PropTypes.element,

    // num, string, element, or an array of those
    node: PropTypes.node
}
```

bool	True or false
Enum	
one0f(any)	Enum types
oneOfType(type array)	Union
Array	
array	
array0f()	
Object	
object	
objectOf()	Object with values of a certain type
instanceOf()	Instance of a class
shape()	
Elements	
element	React element
node	DOM node
Required	
(\cdots) .isRequired	Required

```
])
}
```

Custom validation

```
MyCo.propTypes = {
  customProp: (props, key, componentName) => {
   if (!/matchme/.test(props[key])) {
     return new Error('Validation failed!')
   }
}
```

Also see

```
React website (reactjs.org)

React cheatsheet (reactcheatsheet.com)

Awesome React (github.com)

React v0.14 cheatsheet Legacy version
```

Arrays and objects

```
MyCo.propTypes = {
    list: PropTypes.array,
    ages: PropTypes.arrayOf(PropTypes.number),
    user: PropTypes.objectOf(PropTypes.number),
    user: PropTypes.objectOf(PropTypes.number),
    message: PropTypes.instanceOf(Message)
}

MyCo.propTypes = {
    user: PropTypes.shape({
        name: PropTypes.string,
        age: PropTypes.number
    })
}
Use .array[Of], .object[Of], .instanceOf, .shape.
```
